### UP DOWN PROJECTILE PASSING

Brian Winkel  
Director SIMIODE  
Cornwall NY USA

#### STATEMENT

Shoot a projectile straight up into the air. Determine the maximum height,  $H$ , the given projectile will go. Then consider the time  $T(a)$  ( $0 < a < 1$ ) it takes between when the projectile passes distance  $a \cdot H$  going up and then coming down. Develop  $T(a)$  as a function of  $a$ . Finally, see if there are any relationships involving these two times at which the projectile passes through the same distance, going up and coming down.

#### Articulation

Consider a projectile, projected upwards in a uniform gravitational field with no resistance.

- a) Say the initial velocity is 100 m/sec and the gravitational field is due to earth's gravity, i.e.  $g = -9.81\text{m/sec}^2$  downward.  
We fire a projectile directly up from ground zero.
  - (i) Determine the maximum height,  $H$ , the projectile attains.
  - (ii) For heights  $h = 0, 0.1H, 0.2H, 0.3H, \dots, 0.9H, H$  determine the time (from  $t = 0$ ) it takes to reach height  $h$  (on the UPward path) and the time (from  $t = 0$ ) it takes to reach height  $h$  again (on the DOWNward path). Remember, what goes up must come down!
  - (iii) Look at the numbers you get and make a conjecture about the relationship between these times and the height  $h$ .
- b) Test your conjecture with another initial velocity. Do you get the same results? the same relationship? Does the initial velocity seem to enter your relationship?
- c) Verify your conjecture you made in (a) (iii) for the general equation for a projectile fired vertically with constant acceleration  $a$ , initial velocity  $v_0$ , and initial vertical displacement  $x_0$ .
