SALT WATER TANK MODELING

Brian Winkel
Director SIMIODE
Cornwall NY USA

STATEMENT

Consider the following situations and address the issues raised.

SITUATION 1: At time $t = 0$ a tank contains Q_0 lb of salt dissolved in 100 gal of water. Assume that water containing $\frac{1}{4}$ lb of salt per gallon is entering the tank at a rate of 3 gal/mm, and that the well-stirred solution is leaving the tank at the same rate.

- Describe what you think will happen to the amount of salt in the tank over time, perhaps with a verbal description or a plot.
- Describe the rate at which the salt water is being added to the tank and "subtracted" from the tank as a function of time t in s.
- Write out a differential equation with initial condition which describes the rate of change of salt in the tank, i.e. $Q'(t)$.
- Find an expression for the amount of salt $Q(t)$ in the tank at time t .
- Describe the long term behavior of the amount of salt in the tank. Tell why this makes sense.
- Determine the maximum or maximum possible amount of salt in the tank over time.
- Determine the time when the amount of salt in the tank is at 75% of the maximum possible in (e).

Let us consider a variation on SITUATION 1:

SITUATION 2: At time $t = 0$ a tank contains Q_0 lb of salt dissolved in 100 gal of water. Assume that water containing $\frac{1}{4}$ lb of salt per gallon is entering the tank at a rate of 3

gal/min, and that the well-stirred solution is leaving the tank at the rate of 3.5 gal/min. Let $Q(t)$ be the number of pounds of salt in the tank at time t min.

- (a) Describe what you think will happen to the amount of salt in the tank over time, perhaps with a verbal description or a plot.
- (b) Describe the rate at which the salt water is being added to the tank and “subtracted” from the tank as a function of time t in min.
- (c) Write out a differential equation with initial condition which describes the rate of change of salt in the tank, i.e. $Q'(t)$.
- (d) Find an expression for the amount of salt $Q(t)$ in the tank at time t .
- (e) Describe the long term behavior of the amount of salt in the tank. Tell why this makes sense.
- (f) Determine the maximum or maximum possible amount of salt in the tank over time.
- (g) Determine the time when the amount of salt in the tank is at 75% of the maximum possible in (e).

Finally, let us consider a scenario which is quite different:

SITUATION 3: A 1200 gal tank has 400 gal of water in it containing exactly 20 lb of salt at the start of the process. Salt water is being added to the tank. The concentration of the salt in the water being added is 0.03 lb/gal. This salt water mixture initially is added at a rate of 0.1 gal/s and this rate is steadily increased by 0.02 gal/s each minute. The water in the tank is presumed to mix instantaneously and this mixture is being pumped out of the tank at the rate of 5 gal/s.

Let $S(t)$ be the amount of salt in the tank at time t (s).

- (a) Describe what you think will happen to the amount of salt in the tank over time, perhaps with a verbal description or a plot.
- (b) Describe the rate at which the salt water is being added to the tank as a function of time t in min.
- (c) Write out a differential equation with initial condition which describes the rate of change of salt in the tank, i.e. $S'(t)$.
- (d) Determine the amount of salt in the tank at time t for the first 500 s of operation.
- (e) Plot the amount of salt in the tank as a function of time t .
- (f) What is the minimum amount of salt in the tank during the first 500 s of operation?
